## ABSTRACT

Seasonal age composition summaries of the Pacific sardine in numbers of fish by year class and age are presented in graphic form by port or region of landing for the seasons of 1932-33 through 1959-60. A pictorial history of the sardine fishery for 28 years is thus presented in the bar charts, which illustrate the relative importance of certain year classes in the seasonal catch totals, and in the fluctuations of those totals over this period.

Estimates of the age composition of the commercial catch of the Pacific sardine *Sardinops caerulea* (Girard) are available over 28 seasons from five ports or four regions<sup>1</sup> of landing. These data have been published in separate papers which have recently been assembled under a single cover (Wolf<sup>2</sup>). Age composition data from that report form the basis of the figures presented herein.

Each figure consists of one or more seasonal age summaries of a port or

region presented as a bar chart. Each season's bar chart represents the numbers of fish landed in millions by successive year classes. At the bottom of each figure an age scale has been added. For identification, each year class retains a characteristic pattern of markings on its bar, which represent that year class during its appearance in the landings, regardless of port or season.

Data from ports in British Columbia, Washington, and Oregon have been combined to form seasonal age composition summaries from the Pacific Northwest for the seasons of 1941-42 through 1948-49. These are shown in figures 1 and 2. Seasonal summaries from San Francisco for 1940-41 through 1950-51 are presented in figures 3 through 5. Monterey summaries from 1932-33 through 1952-53 plus 1954-55, 1958-59, and 1959-60 appear in figures

<sup>1</sup>Pacific Northwest totals include data from British Columbia, Washington, and Oregon ports. From 1956-57 through 1959-60 seasons, port summaries have represented regional totals. The major port of the region has been used to designate the region. Details of regional apportionment are given in Daugherty and Wolf, 1960, p. 189.

6 through 15. In figures 16 through 30 the summaries for San Pedro from 1932-33 through 1959-60 are shown. Ensenada summaries from 1951-52 through 1959-60 appear in figures 31 and 32.

These figures present a graphic history of the Pacific sardine catch over 28 seasons and illustrate general trends of production and age composition in the fishery. For example, in the Pacific Northwest the rapid decrease in total landings was accompanied by a gradual increase in average age over the eight seasons, 1941-42 through 1948-49. In San Francisco a similar pattern occurred during 11 seasons. Monterey summaries show a gradual increase in fishery production, reaching a peak in the early 1940's with a stable average age, followed by a decrease in catch and an increase in average age. San Pedro is the only port for which consecutive seasonal summaries over the entire period from 1932-33 through 1959-60 are available. These exhibit fluctuations similar to those at Monterey, but with lesser amplitudes. Ensenada summaries indicate a gradual increase in landings through the 1950's. This is the reverse of trends in more northern areas and undoubtedly resulted from fishery expansion rather than a population increase in this area. The average age of fish at Ensenada, though usually lower than that of San Pedro during

this period, has remained relatively stable.

Certain year classes of sardines were distinctly above the average in abundance. Whenever one or more of these year classes have appeared in the catch, the total catch has increased. In Monterey and San Pedro, the 1931 and 1932 classes were above average in abundance. The four year classes spawned from 1936 through 1939 were responsible for the good production of sardines at all ports in the early 1940's. The year classes produced from 1940 through 1945 were above the 28-year average in numbers, but they were not large enough to sustain the level of catch established by their four predecessors. The 1946, 1947, and 1948 classes were somewhat above average in abundance but were followed by extremely weak classes in 1949 and 1950. Subsequent to 1950, all year classes have been markedly below the 28-year average in abundance, with only the 1952 and 1956 classes showing even moderate success.
